

ABSTRACT

Multiplying circuits 101 to 105, storage circuits
5 111 to 115, first selection circuits 131 to 135, adding
circuits 121 to 125 and second selection circuits 141
to 145 arranged on 16-stage data paths constitute
calculation circuits to execute correlation processing
on respective data paths. 16-bit codes that are basic
10 structures of a PSC and SSC generated in code generating
circuit 170 as despread codes are constant in
repetition characteristics of positive bits and negative
bits, and it is thus possible to execute the correlation
processing on received data with a one-chip mutual shift
15 in sixteen calculation circuits. It is thereby possible
to execute the correlation processing at desired timings
in the first step, second step and third step processing.
